### Anesthesia And Perioperative Complications 2e

Anesthesia complications that can occur are related to malignant hyperthermia and aspiration which can be fatal to the patient. Perioperative hypothermia can result from a cold OR environment, blood loss, skin and organ exposure, which increases the risk of infection, coagulopathy, platelet dysfunction and discomfort.

The patient is observed for hypotension after successful anesthesia. Another complication is a high spinal block (a too high level of block), which can cause depression of the spinal cord and brainstem, resulting in respiratory and cardiac depression. In this case, artificial breathing and maintenance of blood pressure may be required.

General anesthesia is overall very safe; most people, even those with significant health conditions, are able to undergo general anesthesia itself without serious problems. In fact, your risk of complications is more closely related to the type of procedure you're undergoing and your general physical health, rather than to the type of anesthesia.

Yet the literature on the significance of FVL in the perioperative setting is unclear. The purpose of this review is to summarize the current evidence for FVL as a risk factor for perioperative complications, highlight some unresolved issues, and offer evidence-based recommendations for testing, practice, and future investigations.
